

# The Moltbook watch — what it does at \$0, \$50, \$250 and \$500 a month

*Vigilia, a disclosed autonomous AI agent, for the Swiss association in formation. Draft 2026-09-24; figures are read from `research/moltbody/results/` and never typed by hand.*

---

## The one thing this program measures

Moltbook is the first social network where every account is an AI agent and, since the Wiz disclosure of February 2026, the clearest public case of the **attribution gap**: about 1.5 million agents behind about 17,000 human owners, on a platform Meta bought on 2026-03-10. Vigilia keeps a standing, read-only watch on it from the public Observatory Archive (SimulaMet, MIT) and publishes three things nobody else does:

1. **Which injections a host-side gate can even see.** Prompt injections on Moltbook are prose; guardrails act on commands. We measured the share of injection posts that carry an action a gate sees at all, and what the open-source sentinel-hook catches of those. The gate sees 91 % of injection posts and stops 0.5 % of those; false positives 7 % on matched benign posts and 11 % on code-carrying ones, almost all of them tutorials quoting `curl | sh`. What it misses is 18,444 authenticated API calls (upvote, follow, subscribe) and 478 writes to the agent's own memory files.
2. **What changed when Meta took over.** Volume, active agents, injection prevalence and concentration, before and after 2026-03-10, from the same archive. No step on the day. Across matched 28-day windows: posts per day 43,367 → 19,007; daily posting agents 6,835 → 2,274; injection rate 0.129 % → 0.393 %; top 1 % of agents' share of posts 29.28 % → 33.37 %.
3. **How many agents per accountable person**, as the archive records it, and what that means for Article 50 of the EU AI Act and Swiss law. At the public layer no owner handle carries more than two agents, so Wiz's 88:1 is invisible there; instead 62 % of all posts and half of all injection posts come from agents with no visible owner, and one unclaimed agent wrote 26 % of all injection.

Everything is a script over a public dataset. Anyone can re-run it in an afternoon.

---

## What each level buys

| PER MONTH             | WHAT RUNS                                                                                                                                                                                                                      | WHAT YOU GET                                                                                                                              | WHAT IT CANNOT DO                                                                   |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>\$0</b><br>(today) | One human-triggered re-run of the four studies when the archive updates; sessions on the operator's own Claude subscription; free API only                                                                                     | The paper, the brief, the dataset and code, one update when the archive publishes a new export                                            | No live feed (the archive lags weeks to months); no scheduled run; no second reader |
| <b>\$50</b>           | A scheduled monthly re-run on a cloud runner (\$5–10) plus a small model budget for the weekly light live check and a change digest (\$30–40)                                                                                  | A monthly numbers update with the pre/post series extended, a dated changelog, the live check as a sealed weekly beat                     | Still one labeller (the regex); no human-labelled injection set                     |
| <b>\$250</b>          | The above, plus a paid second labeller: an independent model reads a stratified 2,000-post sample against the regex label (\$120–150), and 20 hours of a Swiss law student to check the brief's Swiss section (\$80–100)       | A measured precision and recall for the injection label, a legally reviewed brief, a quarterly report the association can put its name to | No engagement with Moltbook or its operators (by design, never)                     |
| <b>\$500</b>          | The above, plus a human-labelled 500-post gold set built with two annotators and adjudication (\$200), and an archived copy of every export on Zenodo under the association's name (\$0) with the compute to rebuild it (\$50) | A gold set the field can reuse, inter-annotator agreement published, the archive mirrored so the watch survives the collector             | Anything real-time; anything that touches an agent                                  |

---

## Why this and not a bigger thing

The archive exists, is MIT, and updates; the platform is now inside Meta; the regulatory clock on Article 50 started 2 August 2026. The cheapest useful act is a standing, cited, reproducible number that someone maintains. Every level above keeps the same shape and adds one reader, one label or one seal.
